Every tree with n

vertices has n-1edges.

Trees

Kraft inequality: If the depths of the leaves of a binary tree are

$$d_1, \dots, d_n$$
:  

$$\sum_{i=1}^{n} 2^{-d_i} \le 1,$$

and equality holds only if every internal node has 2 sons.

#### Recurrences

Master method:

$$T(n) = aT(n/b) + f(n), \quad a \ge 1, b > 1$$

If  $\exists \epsilon > 0$  such that  $f(n) = O(n^{\log_b a - \epsilon})$ then

$$T(n) = \Theta(n^{\log_b a}).$$

If 
$$f(n) = \Theta(n^{\log_b a})$$
 then 
$$T(n) = \Theta(n^{\log_b a} \log_2 n).$$

If  $\exists \epsilon > 0$  such that  $f(n) = \Omega(n^{\log_b a + \epsilon})$ , and  $\exists c < 1$  such that  $af(n/b) \leq cf(n)$ for large n, then

$$T(n) = \Theta(f(n)).$$

Substitution (example): Consider the following recurrence

$$T_{i+1} = 2^{2^i} \cdot T_i^2, \quad T_1 = 2.$$

Note that  $T_i$  is always a power of two. Let  $t_i = \log_2 T_i$ . Then we have

$$t_{i+1} = 2^i + 2t_i, \quad t_1 = 1.$$

Let  $u_i = t_i/2^i$ . Dividing both sides of the previous equation by  $2^{i+1}$  we get

$$\frac{t_{i+1}}{2^{i+1}} = \frac{2^i}{2^{i+1}} + \frac{t_i}{2^i}.$$

Substituting we find

$$u_{i+1} = \frac{1}{2} + u_i, \qquad u_1 = \frac{1}{2},$$

which is simply  $u_i = i/2$ . So we find that  $T_i$  has the closed form  $T_i = 2^{i2^{i-1}}$ . Summing factors (example): Consider the following recurrence

$$T(n) = 3T(n/2) + n$$
,  $T(1) = 1$ .

Rewrite so that all terms involving Tare on the left side

$$T(n) - 3T(n/2) = n.$$

Now expand the recurrence, and choose a factor which makes the left side "telescope"

$$1(T(n) - 3T(n/2) = n)$$
$$3(T(n/2) - 3T(n/4) = n/2)$$
$$\vdots \qquad \vdots$$

Let  $m = \log_2 n$ . Summing the left side we get  $T(n) - 3^m T(1) = T(n) - 3^m =$  $T(n) - n^k$  where  $k = \log_2 3 \approx 1.58496$ . Summing the right side we get

 $3^{\log_2 n - 1} (T(2) - 3T(1) = 2)$ 

$$\sum_{i=0}^{m-1} \frac{n}{2^i} 3^i = n \sum_{i=0}^{m-1} \left(\frac{3}{2}\right)^i.$$

Let  $c = \frac{3}{2}$ . Then we have

$$n \sum_{i=0}^{m-1} c^{i} = n \left( \frac{c^{m} - 1}{c - 1} \right)$$
$$= 2n(c^{\log_{2} n} - 1)$$
$$= 2n(c^{(k-1)\log_{c} n} - 1)$$
$$= 2n^{k} - 2n.$$

and so  $T(n) = 3n^k - 2n$ . Full history recurrences can often be changed to limited history ones (example): Consider

$$T_i = 1 + \sum_{j=0}^{i-1} T_j, \quad T_0 = 1.$$

Note that

$$T_{i+1} = 1 + \sum_{j=0}^{i} T_j.$$

Subtracting we find

$$T_{i+1} - T_i = 1 + \sum_{j=0}^{i} T_j - 1 - \sum_{j=0}^{i-1} T_j$$
  
=  $T_i$ .

And so 
$$T_{i+1} = 2T_i = 2^{i+1}$$
.

Generating functions:

- 1. Multiply both sides of the equation by  $x^i$ .
- 2. Sum both sides over all i for which the equation is valid.
- 3. Choose a generating function G(x). Usually  $G(x) = \sum_{i=0}^{\infty} x^i g_i$ .
- 3. Rewrite the equation in terms of the generating function G(x).
- 4. Solve for G(x).
- 5. The coefficient of  $x^i$  in G(x) is  $g_i$ . Example:

$$g_{i+1} = 2g_i + 1, \quad g_0 = 0.$$

Multiply and sum:

$$\sum_{i\geq 0}^{\infty} g_{i+1} x^i = \sum_{i\geq 0} 2g_i x^i + \sum_{i\geq 0} x^i.$$

We choose  $G(x) = \sum_{i \geq 0} x^i g_i$ . Rewrite

$$\frac{G(x) - g_0}{x} = 2G(x) + \sum_{i \ge 0} x^i.$$

$$\frac{G(x)}{x} = 2G(x) + \frac{1}{1-x}.$$

Solve for 
$$G(x)$$
:
$$G(x) = \frac{x}{(1-x)(1-2x)}.$$

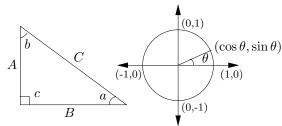

Expand this using partial fractions: 
$$G(x) = x \left( \frac{2}{1-2x} - \frac{1}{1-x} \right)$$
$$= x \left( 2 \sum_{i \geq 0} 2^i x^i - \sum_{i \geq 0} x^i \right)$$
$$= \sum_{i \geq 0} (2^{i+1} - 1) x^{i+1}.$$

So 
$$g_i = 2^i - 1$$
.

#### Partial Fractions

Let N(x) and D(x) be polynomial functions of x. We can break down N(x)/D(x) using partial fraction expansion. First, if the degree of N is greater than or equal to the degree of D, divide N by D, obtaining

$$\frac{N(x)}{D(x)} = Q(x) + \frac{N'(x)}{D(x)},$$

where the degree of N' is less than that of D. Second, factor D(x). Use the following rules: For a non-repeated factor:

$$\frac{N(x)}{(x-a)D(x)} = \frac{A}{x-a} + \frac{N'(x)}{D(x)},$$

where

$$A = \left[\frac{N(x)}{D(x)}\right]_{x=a}.$$

For a repeated factor:

$$\frac{N(x)}{(x-a)^m D(x)} = \sum_{k=0}^{m-1} \frac{A_k}{(x-a)^{m-k}} + \frac{N'(x)}{D(x)},$$

$$A_k = \frac{1}{k!} \left[ \frac{d^k}{dx^k} \left( \frac{N(x)}{D(x)} \right) \right]_{x=a}.$$

$$A(x) = \sum_{i=0}^{\infty} a_i x^i.$$

Exponential power series:

$$A(x) = \sum_{i=0}^{\infty} a_i \frac{x^i}{i!}.$$

Dirichlet power series:

$$A(x) = \sum_{i=1}^{\infty} \frac{a_i}{i^x}.$$

Binomial theorem

$$(x+y)^n = \sum_{k=0}^n \binom{n}{k} x^{n-k} y^k.$$

Difference of like powers:

$$x^{n} - y^{n} = (x - y) \sum_{k=0}^{n-1} x^{n-1-k} y^{k}.$$

For ordinary power series:

$$\alpha A(x) + \beta B(x) = \sum_{i=0}^{\infty} (\alpha a_i + \beta b_i) x^i,$$

$$x^k A(x) = \sum_{i=k}^{\infty} a_{i-k} x^i,$$

$$\frac{A(x) - \sum_{i=0}^{k-1} a_i x^i}{x^k} = \sum_{i=0}^{\infty} a_{i+k} x^i,$$

$$A(cx) = \sum_{i=0}^{\infty} c^i a_i x^i,$$

$$A'(x) = \sum_{i=0}^{\infty} (i+1) a_{i+1} x^i,$$

$$xA'(x) = \sum_{i=1}^{\infty} i a_i x^i,$$

$$\int A(x) dx = \sum_{i=1}^{\infty} \frac{a_{i-1}}{i} x^i,$$

$$\frac{A(x) + A(-x)}{2} = \sum_{i=0}^{\infty} a_{2i} x^{2i},$$

 $\frac{A(x) - A(-x)}{2} = \sum_{i=1}^{\infty} a_{2i+1} x^{2i+1}.$ Summation: If  $b_i = \sum_{j=0}^i a_i$  then

$$B(x) = \frac{1}{1-x}A(x).$$

Convolution:

$$A(x)B(x) = \sum_{i=0}^{\infty} \left(\sum_{j=0}^{i} a_j b_{i-j}\right) x^i.$$

# Stieltjes Integration

If G is continuous in the interval [a, b] and F is nondecreasing then

$$\int_{a}^{b} G(x) \, dF(x)$$

exists. If  $a \leq b \leq c$  then

$$\int_{a}^{c} G(x) \, dF(x) = \int_{a}^{b} G(x) \, dF(x) + \int_{b}^{c} G(x) \, dF(x).$$

If the integrals involved exist

$$\int_{a}^{b} (G(x) + H(x)) dF(x) = \int_{a}^{b} G(x) dF(x) + \int_{a}^{b} H(x) dF(x),$$

$$\int_{a}^{b} G(x) d(F(x) + H(x)) = \int_{a}^{b} G(x) dF(x) + \int_{a}^{b} G(x) dH(x),$$

$$\int_{a}^{b} c \cdot G(x) dF(x) = \int_{a}^{b} G(x) d(c \cdot F(x)) = c \int_{a}^{b} G(x) dF(x),$$

$$\int_{a}^{b} G(x) dF(x) = G(b)F(b) - G(a)F(a) - \int_{a}^{b} F(x) dG(x).$$

If the integrals involved exist, and F possesses a derivative F' at every point in [a, b] then

$$\int_a^b G(x) dF(x) = \int_a^b G(x)F'(x) dx.$$

#### Cramer's Rule

If we have equations:

$$a_{1,1}x_1 + a_{1,2}x_2 + \dots + a_{1,n}x_n = b_1$$

$$a_{2,1}x_1 + a_{2,2}x_2 + \dots + a_{2,n}x_n = b_2$$

$$\vdots \qquad \vdots \qquad \vdots$$

$$a_{n,1}x_1 + a_{n,2}x_2 + \dots + a_{n,n}x_n = b_n$$

Let  $A = (a_{i,j})$  and B be the column matrix  $(b_i)$ . Then there is a unique solution iff  $\det A \neq 0$ . Let  $A_i$  be Awith column i replaced by B. Then

$$x_i = \frac{\det A_i}{\det A}$$

The Fibonacci number system: Every integer n has a unique representation

$$n = F_{k_1} + F_{k_2} + \dots + F_{k_m},$$
  
where  $k_i \ge k_{i+1} + 2$  for all  $i$ ,  $1 \le i < m$  and  $k_m \ge 2$ .

#### Fibonacci Numbers

 $1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, \dots$ Definitions:

$$F_{i} = F_{i-1} + F_{i-2}, \quad F_{0} = F_{1} = 1,$$

$$F_{-i} = (-1)^{i-1} F_{i},$$

$$F_{i} = \frac{1}{\sqrt{5}} \left( \phi^{i} - \hat{\phi}^{i} \right),$$

Cassini's identity: for i > 0:

$$F_{i+1}F_{i-1} - F_i^2 = (-1)^i.$$

Additive rule:

$$F_{n+k} = F_k F_{n+1} + F_{k-1} F_n,$$
  

$$F_{2n} = F_n F_{n+1} + F_{n-1} F_n.$$

Calculation by matrices:

$$\begin{pmatrix} F_{n-2} & F_{n-1} \\ F_{n-1} & F_n \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}^n.$$
